The hazard ATEX - Explosive Atmospheres

Solvent or dust concentration in an area may create a risk of explosion; such an area is thus classified as an ATEX zone.

Example of activities presenting such a risk:
- Handling over compounding tanks (fine chemistry, pharmaceuticals...)
- Sampling from solvent tanks
- Transferring flammable substances from a tanker lorry
- Cleaning with solvents
- Packing, filling hoppers or weighing powders
- Manufacturing explosive products

In an ATEX zone, an explosion may result from objects that are charging static electricity and suddenly discharging thus creating a spark.

Therefore, any object entering an ATEX zone shall be designed and set up in order not to accumulate static electricity. It is thus called “static dissipative” or “conductive”, often also wrongly called “antistatic”.

Beware: PPE (an thus gloves) are excluded from the scope of the ATEX 94/9/EC Directive. THEY ARE NOT MARKED AND CANNOT BE CERTIFIED.

A person working in an ATEX zone must wear adequate clothing and shoes in order to be permanently earthed, thus not able to discharge static electricity that he/she produces through his/her own movements.

The 1999/92/CE directive

The 1999/92/CE Directive defines the ATEX Zones and the obligations of the employer to protect the employees from potential explosion in these areas.

Clothing and Gloves in ATEX Zones

According to the guideline CEI 60079-32-1:2013 - Explosive Atmospheres - Electrostatic Hazards, this classification in Zones enables the employer to determine whether static dissipative gloves are necessary.

MIE (Minimum Ignition Energy) of gasses or dusts in the atmosphere.

Groups of gases IIA, IIB, IIC : propane, ethylene and hydrogen types.

Do not mix up! : a protective glove never protects against a risk of explosion! A regular glove is sometimes not good enough to dissipate charges and could be a risk in ATEX Zone if it can accumulate charges and create a spark. Therefore, in order to prevent this risk, acceptable electrostatic properties are required for the glove.

Protective Gloves used in ATEX Zones

According to the PPE Directive 89/686/CE – Annex 2 – 2.6, if protective gloves are necessary in an ATEX Zone to protect against handled chemicals or mechanical risks, “they must be so designed and manufactured that they cannot be the source of an electric, electrostatic or impact-induced arc or spark likely to cause an explosive mixture to ignite”.

ATEX 1999/92/EC Directive : workers must be provided with appropriate working clothes consisting of materials which do not give rise to electrostatic discharges that can ignite explosive atmospheres.
Electrostatic Properties

The electrostatic properties of a glove shall be assessed through the vertical leakage resistance (in Ohm - Ω) according to EN 16350:2014 standard.

The CEI 60079-32-1:2013 (6.1 – Table 1) guideline provides the definition of electrostatic properties of various objects (below for clothing) at 25% relative humidity.

<table>

<td>≥10⁸Ω</td>
</tr>
</tbody>
</table>

(1) Often wrongly called “antistatic”.
(2) For gloves made of insulative material to work on live electrical lines (EN 60903).
(3) Also called “vertical resistance”.

Measurement of electrostatic properties

Surface resistance
Resistance in Ohms (Ω) of the material's surface between two electrodes placed on its surface, under a voltage of 100V +/-5 V

Vertical resistance
Resistance in Ohms (Ω) through the material between two electrodes placed over the opposite surfaces, under a voltage of 100 V +/- 5 V
EN 16350:2014 - Protective Gloves
Electrostatic Properties

This standard concerns requirements for gloves in ATEX Zones.
It does not concern:

- Gloves used to protect electronic devices against electrostatic risks, such as in the electronic industry (EN 61340-5-1 standard for example).
- Insulative gloves for live working (EN 60903).
- Gloves for welders (EN 12477).

The electrostatic properties alone are not sufficient to ensure safety. The gloves’ wearer must be earthed through adequate dissipative shoes and a dissipative floor.

Test Method
Relative humidity: (25 +/- 5)%; Air temperature: (23 +/- 1)°C.
If the glove is too small to cut out the required test piece, the test device of the EN 61340-2-3 standard may be used, since it accepts a smaller test piece.
Measurement done on 5 test pieces, all must pass the vertical resistance limit.

Requirements
Vertical resistance \( < 1,0 \times 10^8 \ \Omega \) \(^{(2)}\).
Design:
No conductive materials (eg. metal rivets).
Label or reflective strips shall be permanently attached around all edges.
No hook and loop tightening systems.

Information from the manufacturer
No specific pictogramme, no specific marking on the glove.

The information for use must inform about the test results and the test conditions and have the following warnings:
- The person wearing static dissipative gloves shall be properly earthed eg. By wearing adequate footwear.
- Static dissipative gloves shall not be unpacked, opened, adjusted or removed whilst in flammable or explosive atmospheres or while handling flammable or explosive substances\(^{(3)}\).
- The electrostatic properties of the gloves might be adversely affected by ageing, wear, contamination and damage, and might not be sufficient for oxygen enriched flammable atmospheres where additional assessments are necessary.

\(^{(1)}\) The lower the relative humidity, the less dissipative the glove. 25% relative humidity corresponds to a dry climate, thus severe conditions that is certainly not representative of all situations in the workplace.

\(^{(2)}\) This value is severe, we can see that gloves measured at 1012 \( \Omega \) are presently used in numerous ATEX Zones bringing a sufficient safety.

\(^{(3)}\) Such handling may cause triboelectric frictions that may cause a spark to occur.
History of requirements on electrostatic properties of gloves

At the beginning, from 1994 to 2003
The volume resistivity test is described in the EN 388 standard (protective gloves against mechanical risks) at a relative humidity of 50%. The requirement is: < 10^9 Ohm.cm.

From 2003 to 2013
The electrostatic properties are included in EN 420 standard (General requirements for protective gloves).
Tests according to EN 1149-1 (surface resistance), EN 1149-2 (vertical resistance) or EN 1149-3 (decay time), for clothes, may be used for gloves.
No requirements; the result must be included in the information for use without pictogram.

As a comparison, from 2006 (EN 1149-5 standard) the requirement for clothes is a surface resistance measured according to the EN 1149-1 of < 2,5 10^9 Ohm measured at low relative humidity (25%), and/or a decay time < 4 seconds according to EN 1149-3.

In 2013
Publication of the new specific standard on electrostatic properties of gloves EN 16350.

Design and selection of gloves for ATEX Zones

First of all the glove must be selected to cover the chemical or mechanical risks in the workplace, still preserving a good functionality (dexterity, comfort).

Most of the gloves presently used in ATEX Zones for chemical protection (in neoprene or nitrile) do not pass the requirement of the EN 16350 standard; only specially designed gloves with conductive yarns in the textile liner and conductive fillers in the elastomer compound would pass this requirement.

Special materials such as butyl or PVA usually pass the requirement, if the textile liner is adapted.

SYNAMAP’s guideline to the users

It is certain that the test is severe and consider highly critical situations.

A 25% relative humidity corresponds to the special case of cold, ventilated or dehydrated areas (case of preparations sensitive to humidity such as in pharmaceutical or cosmetics industries).

Note: Moreover, in most cases, the gloves are quickly wet inside, especially if liquidproof.

For present or potential users of gloves in ATEX
- Check that the ATEX Zone effectively requires static dissipative gloves.
- Require the result of vertical resistance measured at the lowest relative humidity effectively found in the ATEX Zone.
- Make sure that the gloves are fulfilling the design requirements (no metal parts such as tightening loops, no free materials such as labels, no hook and loop devices...).
- Make sure that the instructions for a safe use are respected: the gloves must not be donned, tightened or taken out of their packaging in the ATEX Zone, they must not be washed, they must be often replaced...
